

## Chapter(10)

Sonic Log:

---

Dr.Abdul hussien Alattabi.

---

The *Sonic Log* measures the acoustic transit time,  $\Delta t$ , of a compressional sound wave traveling through the porous formation. The logging tool consists of one or more transmitters and a series of receivers. The transmitters act as sources of the acoustic signals which are detected by the receivers. The time required for the signal to travel through one foot of the

rock formation is the acoustic transit time,  $\Delta t$ . The acoustic travel time, then, is the reciprocal of the sonic velocity through the formation. The units of  $\Delta t$  are micro-seconds/ft ( $\mu\text{sec}/\text{ft}$ ) or millionths of a second per foot.

There are several ways to interpret the sonic log measurements. One of the most common interpretation formulae is the Wyllie Time-Average Equation:

$$\phi_{sl} = \frac{\Delta t_{sl} - \Delta t_{ma}}{\Delta t_f - \Delta t_{ma}} \dots \dots \dots \text{Equ.} \dots 1$$

Where:

- $\phi_{sl}$  is the porosity from the sonic log (log measurement) , fraction
- $\Delta t_{sl}$  is value of the acoustic transit time measured by the sonic log,  $\mu\text{sec}/\text{ft}$
- $\Delta t_{ma}$  is value of the acoustic transit time of the rock matrix measured in the laboratory,  $\mu\text{sec}/\text{ft}$
- $\Delta t_f$  is value of the acoustic transit time saturating fluid measured in the laboratory,  $\mu\text{sec}/\text{ft}$
- The presence of hydrocarbons in the reservoir rock results in an over prediction of porosity measured by the sonic log and some corrections may be required. These corrections take the form:
  - Gas:  $\phi_{sonic} = 0.7 \phi_{sl} \dots \dots \dots \text{Eq2}$
  - Gas:  $\phi_{sonic} = 0.7 \phi_{sl} \dots \dots \dots \text{Eq3}$

or, for oil

$\dots \dots \dots \text{Oil: } \phi_{sonic} = 0.9 \phi_{sl} \dots \dots \dots \text{Eq4}$

Table 1- has typical values of the acoustic transit time for different reservoir formations and commonly encountered reservoir fluids.

**Table(1)-Typical Acoustic Transit Times for Sonic Log Interpretation**

Heading	$\Delta t_{ma}$ ( $\mu\text{sec}/\text{ft}$ ) Range	$\Delta t_{ma}$ ( $\mu\text{sec}/\text{ft}$ ) Commonly Used	$\Delta t_f$ ( $\mu\text{sec}/\text{ft}$ ) Range	$\Delta t_f$ ( $\mu\text{sec}/\text{ft}$ ) Commonly Used
Sandstone	55.5 – 51.0	55.5 or 51.0	-----	-----
Limestone	47.8 – 43.5	47.5	-----	-----
Dolomite	43.5	43.5	-----	-----
Anhydrite	50.0	50.0	-----	-----
Salt Formation	66.7	67.0	-----	-----
Fresh Water Based Drilling Fluid	-----	-----	189.0	189.0
Salt Water Based Drilling Fluid	-----	-----	185.0	185.0
Gas	-----	-----	920.0	920.0
Oil	-----	-----	230.0	230.0
Casing (Iron)	-----	-----	57.0	57.0

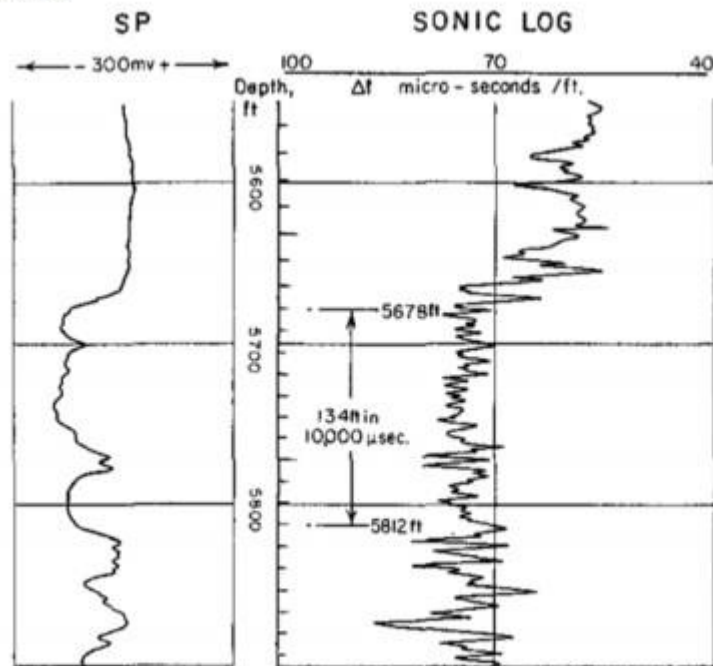

Other empirically based equations exist for sonic log interpretation. One form of an alternative equation is

$$\phi_{\text{sonic}} = C * \{(\Delta t_{sl} - \Delta t_{ma}) / (\Delta t_{sl}) \dots \dots \dots \text{Eq}(5)$$

In this equation, the value of C is in the range of 0.625 to 0.700 and is determined by calibrating the equation to known porosity, such as, to core data when a well is both cored and logged. In Equation 3.12 and Equation 3.13,  $\phi_{\text{sonic}}$  is the final interpreted porosity from the sonic log.

Q: Find the porosity from sonic log for interval of sand stone(5678ft-5812ft)...we the fluid is fresh water.

5. Estimate the average porosity of the thick sand interval shown on the sonic log of figure below. (20 pts).

[Wyllie's Equation:  $\phi = (\Delta t - \Delta t_{ma}) / (\Delta t_f - \Delta t_{ma})$ ,  $\Delta t_{ma} = 55.5 \mu\text{sec}/\text{ft}$  for sandstone; the average fluid slowness  $\Delta t_f$  used is  $189 \mu\text{sec}/\text{ft}$ ;  $\Delta t$  is called internal travel time or slowness,  $\mu\text{sec}/\text{ft}$ ]

Answer:

$$\phi_{sl} = \frac{\Delta t_{sl} - \Delta t_{ma}}{\Delta t_f - \Delta t_{ma}}$$

The average  $\Delta t_{log}$  ( $\mu\text{sec}/\text{ft}$ ) for interval (5678-5812)ft =  $80 \mu\text{sec}/\text{ft}$ .

$\Delta t_f$  for fluid fresh water = 189  $\mu\text{sec}/\text{ft}$

The bed is sandstone so  $\Delta t_{ma}$  from table = 55.5  $\mu\text{sec}/\text{ft}$ .

$$\text{i.e } \phi_{sl} = \frac{(80 \mu\text{sec}/\text{ft} - 55.5 \mu\text{sec}/\text{ft})}{(189 \mu\text{sec}/\text{ft} - 55.5 \mu\text{sec}/\text{ft})} = \frac{24.5}{133.5} = 0.184 = 18\%$$

---

This porosity is the primary porosity

Total porosity =  $\phi_T$

$\phi_T = (\phi_N + \phi_d)/2$  for oil zone

$\phi_T = \text{sequare root of } (\phi_N + \phi_d)/2$  for gase zone

.....

Secondary porosity = Total porosity - Sonic porosity

This mean the fractures, dissolution...etc.
